PROLOGO

Para la descripción del Observatorio y los aparatos, remitimos al lector al número 1.^o de las *Notas Geofísicas y Meteorológicas* que se publicó en 1924, al dar cuenta de la fundación del nuevo Observatorio.

En este volumen damos a luz detalladamente las observaciones de Bogotá hechas en 1930, siéndonos imposible el dar numéricamente los datos de los aparatos registradores, ya por falta de personal, ya por las condiciones económicas.

En cambio, hemos procurado reunir las observaciones de algunas estaciones secundarias que empezaron a funcionar en 1924, pues es imposible publicarlas extensamente, por los gastos que esto supone.

Desde las 6 a. m. hasta las 8 p. m. anótanse de dos en dos horas las indicaciones de los aparatos de este Observatorio Central; los promedios están calculados de esas ocho observaciones. Nuestro deseo sería utilizar todos los datos de los registradores, mas esto es imposible con el escaso personal del Observatorio.

Hemos aplicado todas las correcciones comunes de la temperatura, instrumentos, etc., incluyendo en la presión atmosférica la de la gravedad normal de la latitud de 45°, conforme explicamos en los *Anales* de 1923.

La reducción al nivel del mar, tratándose de Bogotá, cuya altura es de 2,645 metros, y no conociéndose todavía métodos satisfactorios, cuando se trata de elevaciones tan grandes, la hemos omitido, siguiendo en esto el ejemplo de otros observatorios. Remitimos al lector a lo escrito en las *Notas Geofísicas*, página 64, sobre esta debatida cuestión.

Cuenta el Observatorio con los principales aparatos de meteorología tanto de lectura directa como registradores.

No siendo necesario conocer con toda exactitud las coordenadas del Observatorio, por no tratarse de trabajos astronómicos de precisión,

hemos adoptado la latitud del Observatorio Astronómico determinada por el doctor Julio Garavito, aumentada en "4", cantidad aproximada que hemos calculado para la distancia de los dos Observatorios.

Las coordenadas son:

Latitud del Observatorio Nacional de San Bartolomé..... 4°35'59"N

Longitud W. de Greenwich..... 74°4'52"65

Altura de los aparatos sobre el nivel del mar:

TEMPESTADES ELECTRICAS

Hay regiones en Colombia donde los fenómenos eléctricos en la atmósfera son frecuentes, como sucede en Popayán y sus inmediaciones, las que han adquirido celebridad por la violencia de las tormentas de esa clase. Según el distinguido P. Job, éstas parecen haber disminuído en aquella ciudad desde la instalación del alumbrado eléctrico. Sea de esto lo que fuere, pues sería necesaria una estadística llevada por muchos años para comprobar el hecho, lo cierto es que en Colombia existe cierta desigualdad en el desarrollo de estos fenómenos, por ser ordinariamente locales en que la topografía influye mucho.

En general las tormentas eléctricas son menos numerosas a grandes alturas, como sucede en las altiplanicies, y se desarrollan con más facilidad en los puntos en que el calor solar se deja sentir con fuerza durante el día, o la circulación atmosférica de las corrientes se presenta más propicia para dar origen al campo eléctrico.

Las observaciones hechas en el Observatorio, hace algún tiempo, con un electrómetro del P. Wulf, nos convencieron acerca de la notable influencia que las corrientes aéreas tienen en el desarrollo del campo eléctrico. Aquí las del Oeste son más propicias y mucho menos las del Este.

En la presente nota nos vamos a fijar en el mecanismo de esas tempestades eléctricas y la explicación más satisfactoria que, en el estado actual de la ciencia, se puede dar de esos fenómenos.

Con Mr. Simpson no dudamos en admitir algunos hechos comprobados por las observaciones y en especial del Observatorio del Ebro, en cuyas publicaciones se hallan datos interesantes. ¿Cómo se forman los campos eléctricos en la atmósfera? ¿Cuál es su origen?

Es un hecho el que el aire se hace conductor por ionización rápida y que los electrones producidos suben con más celeridad que los iones positivos al campo, donde se verifica una concentración de cargas opuestas. Supongamos

una nube con carga positiva, a cierta distancia de la tierra, que también se halla cargada por influencia negativamente.

Con gran violencia se ioniza entonces la atmósfera, precipítanse los electrones hacia la nube, y como los iones positivos apenas se mueven, tendremos que en la parte baja de la nube se concentran las líneas de fuerza. El efecto de esta concentración es el que los electrones vienen a formar una especie de canal por donde suben, llegando a ser la ionización cada vez más intensa. En el momento en que la nube adquiera la intensidad suficiente para producir la descarga, ésta viene con todas las irregularidades que pueda haber en las líneas de fuerza, que dan origen a variadas ramificaciones en el relámpago.

Esta manera de concebir la descarga y el rayo está de acuerdo con las teorías modernas de los electrones e iones, y se confirma experimentalmente con la fotografía de las chispas producidas en los laboratorios al estudiar las descargas eléctricas.

Si la nube está cargada negativamente, y el suelo con electricidad positiva, las líneas de fuerza se prolongan, facilitando la descarga que suele ser completa, mientras que en el caso anterior no lo es.

La fotografía de los relámpagos ha facilitado mucho las investigaciones de las descargas. El doctor Simpson ha estudiado las fotografías de 442 relámpagos, formando la siguiente estadística: 242 tienen ramificaciones descendentes; 3 son ascendentes; 173 no se ramifican, y los demás describen una variedad de curvas indefinibles. Así se ve que las descargas de las nubes con electricidad positiva son más frecuentes.

Una explicación satisfactoria del mecanismo de la tormenta eléctrica es muy difícil, mas la interpretación de las numerosas fotografías de los relámpagos induce a creer que ordinariamente las descargas provienen de las nubes bajas cargadas positivamente. Banerji, en el estudio de las trubonadas que hizo en Bombay,

distingue tres partes en la nube: la parte anterior cargada negativamente, la central positivamente y la posterior negativamente. Si los fenómenos descritos por Banerji son ciertos, la explicación de Simpson tiene sus dificultades, y los observadores Appleton y Chonland las urgirán para defender la estructura bipolar de la nube tormentosa, como ellos proponen.

En general, la atmósfera durante la tormenta eléctrica se presenta muy inestable y perturbada por las corrientes ascendentes que adquieren notable velocidad. Este es un fenómeno ordinario en los trópicos, durante la época de las turbonadas, como pudimos observar con frecuencia en la isla de Cuba.

LA ACELERACION DE LA GRAVEDAD EN BOGOTA

Como nunca se ha determinado el valor de la gravedad en Bogotá, según se nos ha asegurado por personas competentes, y siendo, por otra parte, muy útil el conocer, aunque sea aproximadamente, ese valor, el Reverendo Padre Carlos Ortiz, S. J., profesor de Física del Colegio de San Bartolomé, ha tenido la bondad de redactar el siguiente trabajo, que con mucho gusto publicamos en los *Anales*. A nuestro juicio, mientras no tengamos péndulos con qué determinar medidas absolutas de g , se podrá utilizar el valor hallado por el Padre Ortiz como muy aproximado, dada la gran exactitud con que ha hecho los cálculos.

La ley de la gravitación universal formulada por Newton en su libro de *Philosophiae Naturalis Principia Mathematica* (Londres 1687), se expresa mediante la ecuación

$$F = f \frac{m m'}{r^2} \quad (1)$$

Donde F representa la fuerza con que se atraen dos masas puntiformes m y m' , colocadas a una distancia r . f representa un coeficiente que depende del sistema de unidades que se adopte.

$f = 6,667 \times 10^{-8}$ C. G. S. Valor adoptado por la Asociación Geodésica Internacional.

$f = 6,65 \times 10^{-8}$ C. G. S. Eötvös, 1896.

$f = 6,9864 \times 10^{-8}$ C. G. S. Pointing, 1891.

De esto deducimos que dos gramos colocados a la distancia de un centímetro se atraen con la fuerza de $6,667 \times 10^{-8}$ dinas.

Si llamamos M la masa de la tierra, supuesta esférica y formada de capas de densidad homogénea, R su radio y m una masa cualquiera colocada en su superficie, se demuestra que estas dos masas se atraen con una fuerza

$$F = f \frac{M m}{R^2} \quad (2)$$

La dinámica nos da que

$$F = m \gamma \quad (3)$$

donde F es la fuerza, m una masa cualquiera y γ la aceleración que esta fuerza comunica a dicha masa. Igualando (2) y (3) obtenemos después de suprimir el factor m

$$f \frac{M}{R^2} = \gamma \quad (4)$$

Esta sería la aceleración que comunicaría la atracción de la tierra a una masa cualquiera colocada en su superficie, supuestas las condiciones de homogeneidad y esfericidad antes indicadas.

La masa m , colocada en la superficie de la tierra está además sometida a la aceleración centrífuga que le comunica la rotación de ésta, y a las atracciones de los astros. La influencia de los astros es despreciable; la de la luna, que es la mayor, es del orden de las diezmillonésimas, mientras que la fuerza centrífuga vale alrededor de tres dinas por cada gramo en el ecuador, y varía con la latitud.

La resultante de la aceleración producida por la atracción de la tierra y la de la fuerza centrífuga es lo que se llama aceleración de la gravedad y se suele representar por la letra g .

Como la tierra no es esférica, ni su masa homogénea, ni su densidad suficientemente conocida, el cálculo de g presenta serias dificultades.

Se ha hallado el valor de g experimentalmente por varios métodos. Los principales están fundados en las propiedades del péndulo. Sabemos que el péndulo simple o matemático tiene un periodo de oscilación

$$\tau = \pi \sqrt{\frac{l}{g}}$$

Donde τ representa el tiempo de una oscilación infinitesimal, π la constante de Arquímedes 3.14159..., l , la longitud pendular y g , la aceleración de la gravedad.

El péndulo matemático es irrealizable, pero la mecánica nos da en ciertos casos el valor de la longitud pendular equivalente de algunos

péndulos compuestos como son, verbigracia, el péndulo formado por un hilo fino que lleva en su extremo una esferilla pesada, o el reversible de Kater. Las medidas, a primera vista sencillas, tienen dificultades prácticas que sólo pueden vencer la experiencia y la habilidad de los expertos, y requieren aparatos cuya adquisición no está al alcance de cualquiera. Como, por otra parte, el conocimiento de g es necesario para multitud de usos científicos, se han ideado fórmulas que dan su valor en función de la latitud con la aproximación necesaria para la mayor parte de los cálculos.

Helmert, en 1901, dedujo de la discusión de los valores hallados en 1,603 estaciones, las fórmulas siguientes:

$$g_\phi = 978,030 \left(1 + 0,005302 \sin^2 \phi - 0,000007 \sin^2 2\phi\right) \frac{\text{cm}}{\text{seg}^2}$$

$$g_\phi = 980,616 \left(1 - 0,002644 \cos 2\phi + 0,000007 \cos^2 2\phi\right) \frac{\text{cm}}{\text{seg}^2}$$

Donde ϕ representa la latitud y g_ϕ el valor de g en dicha latitud y al nivel del geoide terrestre.

Más recientemente Bowie, en 1917, dedujo de la discusión de 372 estaciones la fórmula

$$g_\phi = 978,039 \left(1 + 0,005204 \sin^2 \phi - 0,000007 \sin^2 2\phi\right) \frac{\text{cm}}{\text{seg}^2}$$

La Asamblea General de la Unión Geodésica y Geofísica Internacional reunida en Madrid en octubre de 1924 adoptó las dos siguientes:

$$g_\phi = g_e \left(1 + 0,005288 \sin^2 \phi - 0,000006 \sin^2 2\phi\right) \frac{\text{cm}}{\text{seg}^2}$$

$$g_\phi = g_{45} \left(1 - 0,002637 \cos 2\phi + 0,000006 \cos^2 2\phi\right) \frac{\text{cm}}{\text{seg}^2}$$

Siendo g_e y g_{45} la aceleración de la gravedad en la superficie del geoide a las latitudes 0° y 45° , respectivamente.

$$g_e = \begin{cases} 978,038 \frac{\text{cm}}{\text{seg}^2} & \text{Bowie} \\ 978,052 & \text{Helmert} \\ 978,052 & \text{Heiskanen (1924)} \end{cases}$$

$$g_{45} = \begin{cases} 980,621 \frac{\text{cm}}{\text{seg}^2} & \text{Bowie} \\ 980,629 & \text{Helmert} \\ 980,629 & \text{Heiskanen} \end{cases}$$

Aplicando estas fórmulas a la latitud de Bogotá $= 4^\circ 35' 59''$. Deducimos:

$$g = \begin{cases} 978,063 & \text{Fórmulas de Helmert} \\ 978,063 & \end{cases}$$

$$g = 978,072 \quad \text{Fórmula de Bowie.}$$

Aplicando a las fórmulas aceptadas por la Unión Geodésica y Geofísica los valores de g_e y g_{45} hallados por Helmert, Bowie y Heiskanen, hallamos para la latitud de Bogotá.

$$\text{Partiendo de } g_e; g = \begin{cases} 978,071 & \text{Bowie.} \\ 978,085 & \text{Helmert y Heiskanen.} \end{cases}$$

$$\text{Partiendo de } g_{45}; g = \begin{cases} 978,074 & \text{Bowie.} \\ 978,082 & \text{Helmert y Heiskanen.} \end{cases}$$

Bogotá no está al nivel del geoide sino a una altura de 2,640 metros, lo que representa por una parte un alejamiento del centro y por otra un acumulamiento de masa en su base. Para tener cuenta de una y otra circunstancia introducimos dos correcciones debidas a Stokes y a Bourguer que reunidas en una dan el valor

$$\Delta g = (1 - 0,1359 d) 3,086 \cdot 10^{-6} H$$

donde Δg es la corrección que buscamos, d la densidad de las capas comprendidas entre la superficie del geoide y la estación, H la altura de la estación sobre el geoide, medido todo en C. G. S.

Haciendo $d=2,5$ y a $H=264000$ cm.

$$\Delta g = 0,5379$$

Con esta corrección obtengo finalmente para g_b , valor de g en Bogotá, los siguientes valores:

$$g_b = \begin{cases} 977,525 & \text{Fórmulas de Helmert.} \\ 977,525 & \\ 977,534. & \text{Fórmula de Bowie.} \end{cases}$$

Las fórmulas de la Unión Geodésica y Geofísica Internacional me dan:

$$g_b = \begin{cases} 977,533 & \text{Bowie.} \\ 977,547 & \text{Helmert y Heiskanen, partiendo de } g_e. \end{cases}$$

$$g_b = \begin{cases} 977,536 & \text{Bowie.} \\ 977,544 & \text{Helmert y Heiskanen, partiendo de } g_{45}. \end{cases}$$

El valor más aceptable a nuestro juicio es la media obtenida de las dos fórmulas últimas para los valores de g_e y g_{45} hallados por Helmert y Haiskanen, o sea:

$$g_b = 977,546$$

Y este quizás se podría aceptar como provisional mientras se pueden hacer medidas absolutas que merezcan toda confianza.

CARLOS ORTIZ RESTREPO, S. J

Resumen de las observaciones de 1930 en algunas estaciones secundarias.
